

1 Supplementary Materials

2 Supplementary Discussion

3 This supplementary section represents the detailed derivation of the governing equation and
4 the associated boundary conditions, presented in the main text. In case of liquid needle
5 droplet deposition technique the energy imparted by the impinging jet is transformed into
6 internal energy, surface energy, and gravitational energy, in addition to the resistance offered
7 by the medium viscosity and viscous dissipation within the spreading droplet. The energy
8 transferred from the impinging jet to the spreading drop results in equation 1 as follows:

$$\frac{dE_{\text{in}}}{dt} = \frac{d}{dt}(E_{\text{system}} + E_s + E_g) + \frac{d}{dt}(W_{\text{vd}} + W_{\text{mv}}) \quad (1)$$

9 Where, E_{in} , E_{system} , E_s and E_g is the incoming energy available in the liquid jet, the internal
10 energy in the spreading droplet, the surface energy and the gravitational potential energy,
11 respectively, whereas, W_{vd} and W_{mv} is the work due to viscous dissipation and the work
12 associated with medium viscosity, respectively.

13

14 It is to be noted that the kinetic energy of the jet is the only incoming energy, E_{in} to the
15 system. Considering the mass of the incoming liquid as m and velocity of the impacting jet
16 as, v_j , the rate of change of incoming energy transfer can be expressed as,

$$\frac{dE_{\text{in}}}{dt} = \frac{v_j^2}{2} \frac{dm}{dt} \quad (2)$$

17 The internal energy of the spreading droplet is the combination of enthalpy [1] and the ki-
18 netic energy of the jet. If we assume the overall system as isobaric and isothermal system,
19 then from order of magnitude analysis it can be demonstrated that the overall change in the
20 enthalpy is negligible [2]. on the other hand, the internal kinetic energy induced due to the

21 impingement of the jet on the liquid-medium interface can be ignored since the drop surface
 22 area is remarkably greater than the liquid jet cross sectional area. Therefore, as both the
 23 enthalpy and internal kinetic energy are negligible, the internal energy in the system can
 24 be considered as constant. As a result, in equation 1 the transient change in E_{system} can be
 25 ignored.

26

27 The total surface energy of the system can be defined considering the surface energies of the
 28 three interfacial phases, *i.e.*, liquid-solid (drop-substrate), liquid-fluid (drop-medium) and
 29 solid-fluid (substrate-medium) which suggests $E_s = \sigma_{\text{ds}}A_{\text{ds}} - \sigma_{\text{sm}}A_{\text{sm}} + \sigma_{\text{dm}}A_{\text{dm}}$, where, σ
 30 and A represent the surface energy and area for respective interfaces and subscripts d , s and
 31 m denotes the drop, solid and the surrounding medium, respectively. With a spherical drop
 32 shape assumption the rate of change of surface energy can be expressed as,

$$\frac{dE_s}{dt} = 2\pi R\sigma_{\text{dm}}[2h(\theta_d) - \cos\theta_e]\frac{dR}{dt} \quad (3)$$

33 where, $h(\theta_d) = \frac{1 - \cos\theta_d}{\sin^2\theta_d}$ and θ_d and θ_e are the advancing (dynamic) and equilibrium con-
 34 tact angle, respectively.

35

36 During droplet growth, due to the continuous addition of mass, the change in the mass and
 37 the change in the center of gravity of the depositing droplet the consideration of the gravi-
 38 tational forces become mandatory. For an infinitesimal increase of mass, Δm , if the center
 39 of gravity is shifted by Δz , the change in gravitational potential energy can be expressed as,

40 $\Delta E_g = g[(m + \Delta m)(z + \Delta z) - mz]$. After eliminating the negligible products ($\Delta m \cdot \Delta z \approx 0$)

41 the rate of change in potential energy can be expressed as, $\frac{dE_g}{dt} = g \left[m \frac{dz}{dt} + z \frac{dm}{dt} \right]$, where

42 the total mass of the system can be obtained as $m = m_0 + \int_a^b \frac{dm}{dt} dt$. Now considering all

43 the terms the expression for the rate of change in the gravitational potential energy can be

44 expressed as,

$$\frac{dE_g}{dt} = g \left[m \left(\frac{3f(\theta_d)}{4} \frac{dR}{dt} \right) + \frac{R}{4} f(\theta_d) \frac{dm}{dt} \right] \quad (4)$$

45 where, $f(\theta_d) = \frac{2 - \sin^2 \theta_d + 2 \cos \theta_d}{(2 + \cos \theta_d) \sin \theta_d}$.

46

47 The viscosity of the surrounding medium can play a crucial role in confining the spreading of
 48 the droplet. During liquid needle droplet deposition, due to the continuous addition of mass,
 49 the surrounding medium get displaced by the increase in drop volume. Therefore, additional
 50 work has been done by the surrounding medium on the drop-medium interface. The rate
 51 of work due to medium viscosity can be quantified as, $\frac{dw_{mv}}{dt} = \tau V dA$, where τ is the shear
 52 stress which acts normal to the surface, dA , due to the drop spreading velocity, $V = dR/dt$.

53 The shear stress at the drop boundary, i.e. at the liquid-medium interface, can be defined
 54 as $\tau = 2\mu_m \left(\frac{\partial u}{\partial r} \right)_{r=R}$, where, μ_m is the medium viscosity and u is the velocity by which the
 55 surrounding medium is getting displaced. If we consider a lamina of fluid outside the drop
 56 at a distance r , where $r > R$, and implement the mass conservation between surrounding
 57 medium and the droplet, one can obtain the velocity of the surrounding medium adjacent
 58 to the drop boundary as, $u = \frac{R^2}{r^2} \frac{dR}{dt}$. The resultant rate of work due to medium viscosity
 59 can be represented as,

$$\frac{dw_{mv}}{dt} = \left[\frac{4\mu_m}{R} \frac{dR}{dt} \frac{1}{\rho_m} \right] \frac{dm}{dt} \quad (5)$$

60 If we are to consider the internal motion of the liquid layers inside a droplet, the consider-
 61 ation of viscous dissipation force is inevitable. Depending on the magnitude of the contact
 62 angle, two models have been adopted by the researchers: lubrication approximation [3,4] or
 63 boundary layer approximation [5]. De Gennes predicted the viscous dissipation work based
 64 on lubrication approximation. For hydrodynamic drop spreading when the contact angle of

65 the droplet is less than 90° , we follow the De Gennes approach. Based on the lubrication
66 model [3,4], the viscous force per unit length of the three-phase contact line can be expressed
67 as, $F_v = \frac{3\mu_d}{\theta_d} \ln\left(\varepsilon^{-1} \frac{dR}{dt}\right)$, where θ_d is the instantaneous dynamic contact angle, μ_d is the
68 viscosity of the droplet and ε is the ratio of the microscopic length (L_δ) to macroscopic cut-
69 off length (L). In general, L_δ may vary between $1 \mu m$ to $5 \mu m$ whereas L can be defined as
70 the horizontal length scale (R) of the drop [2]. The viscous dissipation work of the circular
71 three phase contact line is $2\pi R F_v$. Therefore, the rate of viscous dissipation work over the
72 three-phase contact line can be expressed as [3, 4],

$$\frac{dw_{vd}}{dt} = 6\pi\mu_d \ln(\varepsilon^{-1}) \frac{R}{\theta_d} \left(\frac{dR}{dt}\right)^2 \quad (6)$$

73 On the other hand, as an alternative to lubrication approximation, boundary layer approach
74 can be taken into consideration for predicting the viscous dissipation for drop-substrate
75 combination of higher contact angle. Boundary layer approximation for viscous dissipation
76 model was suggested by Chandra et al. [5]. Based on the boundary layer approximation
77 model the viscous dissipation work is approximated as, $w_v = \int_a^b \phi \Omega t_c$. [5-7], where ϕ is
78 the viscous dissipation which can be approximated as, $\phi = \mu_d \left(\frac{\partial v_i}{\partial x_k} + \frac{\partial v_k}{\partial x_i}\right) \frac{\partial v_i}{\partial x_k} = \mu_d v_j^2 / \delta^2$,
79 where $\delta = \frac{2D_j}{\sqrt{Re}}$ is the characteristic length scale of the droplet, $\Omega = \pi R^2 \delta$ is the volume of the
80 droplet and $t_c = h_j / v_j = k_{h_j} D_j / v_j$. Therefore, considering the boundary layer approximation,
81 the work done due to viscous dissipation per unit time, over the three-phase contact line,
82 can be expressed as,

$$\frac{dw_{vd}}{dt} = \mu_d v_j \pi k_{h_j} \sqrt{Re} R \frac{dR}{dt} \quad (7)$$

83 Now, considering the lubrication approximation model for the maximum wetting scenario,
84 combining equation 1 to 6, we can form the following governing equation for the drop spread-
85 ing for liquid needle drop deposition technique,

$$\begin{aligned}
& 6\pi\mu_d \ln(\varepsilon^{-1}) \frac{R}{\theta_d} \left(\frac{dR}{dt} \right)^2 + [2\pi R \sigma_{\text{dm}} (2h(\theta_d) - \cos \theta_e) \\
& \quad + (m_0 + \frac{dm}{dt}) g \frac{f(\theta_d)}{4} - \frac{4\mu_m}{R\rho_m} \frac{dm}{dt}] \frac{dR}{dt} \\
& \quad + \frac{dm}{dt} \left[\frac{gRf(\theta_d)}{4} - \frac{v_j^2}{2} \right] = 0
\end{aligned} \tag{8}$$

86 Whereas, considering the boundary layer approximation theory in case of the minimum
87 wetting scenario, combining equation 1 to 5 and 7, we can form the following governing
88 equation for the drop spreading for liquid needle drop deposition technique,

$$\begin{aligned}
& \mu_d v_j \pi k_{h_j} \sqrt{Re} R \frac{dR}{dt} + \left[2\pi R \sigma_{\text{dm}} (2h(\theta_d) - \cos \theta_e) \right. \\
& \quad \left. + (m_0 + \frac{dm}{dt}) g \frac{f(\theta_d)}{4} - \frac{4\mu_m}{R\rho_m} \frac{dm}{dt} \right] \frac{dR}{dt} \\
& \quad + \left[\frac{gRf(\theta_d)}{4} - \frac{v_j^2}{2} \frac{dm}{dt} \right] = 0
\end{aligned} \tag{9}$$

89 The non-dimensional form of governing equation can be expressed as the following equation
90 10 and 11, for lubrication and boundary layer approximation, respectively.

$$\begin{aligned}
& \frac{6\ln(\varepsilon^{-1})}{\theta_d} \frac{R^*}{Re} \left(\frac{dR^*}{dt^*} \right)^2 + \left[\frac{4R^*}{We} (2h(\theta_d) - \cos \theta_e) + \frac{f(\theta_d)G(\theta_d)}{24} (R_0^*)^3 \frac{Bo}{We} \right. \\
& \quad \left. + \frac{k_{h_j} f(\theta_d)}{4} t^* \frac{Bo}{We} + \frac{k_{\mu_m}}{R^*} \frac{8}{Re} \right] \frac{dR^*}{dt^*} + \frac{dm}{dt} \left[\frac{f(\theta_d)}{4} R^* \frac{Bo}{We} \right] = 0
\end{aligned} \tag{10}$$

$$\begin{aligned}
& \frac{k_{h_j}}{4\sqrt{Re}} R^* \frac{dR^*}{dt^*} + \left[\frac{4R^*}{We} (2h(\theta_d) - \cos \theta_e) + \frac{f(\theta_d)G(\theta_d)}{24} (R_0^*)^3 \frac{Bo}{We} + \frac{k_{h_j} f(\theta_d)}{4} t^* \frac{Bo}{We} \right. \\
& \quad \left. + \frac{k_{\mu_m}}{R^*} \frac{8}{Re} \right] \frac{dR^*}{dt^*} + \frac{dm}{dt} \left[\frac{f(\theta_d)}{4} R^* \frac{Bo}{We} \right] = 0
\end{aligned} \tag{11}$$

91 Where, $Re = \rho_d v_j D_j / \mu_d$, $We = \rho_d v_j^2 D_j / \sigma_{dm}$, and $Bo = \rho_d g D_j^2 / \sigma_{dm}$ are Reynolds number,
 92 Weber number and Bond number, respectively; also, $k_{\mu_m} = \mu_m / \mu_d$, $R^* = \frac{R}{D_j/2}$, $R_0^* = \frac{R_0}{D_j/2}$,
 93 $t^* = \frac{t}{D_j/v_j}$ and $G(\theta_d) = \frac{2 - 3 \cos(\theta_d) + \cos^3(\theta_d)}{\sin^3(\theta_d)}$.

94
 95 The spreading of the droplet or the transient variation of the droplet base radius can be pre-
 96 dicted by numerically solving (e.g. 4th order Runge Kutta (RK4) method) either equation
 97 10 or 11, with corresponding contact angle value and appropriate initial boundary condition.
 98 For this study we have chosen the initial condition as the drop radius at the moment when
 99 the jet makes the first impact on the substrate, i.e., the splat shape of the droplet. Here, we
 100 assume that the volume of the splat shape droplet is equivalent to the volume of the liquid
 101 jet before the impact.

102
 103 To determine the initial spreading diameter of the splat, we can further employ the energy
 104 balance equation, *i.e.* the energy available in the jet (kinetic energy) before deposition and the
 105 energy transferred (surface energy, viscous dissipation work and work done due to medium
 106 viscosity) to form the splat droplet shape (initial drop shape). The kinetic energy of the
 107 impacting jet can be calculated as, $\frac{1}{2} m v_j^2$. We can define the surface energy considering the
 108 splat shape as, $\frac{\pi}{4} D_0^2 \sigma_{dm} (1 - \cos \theta_e)$. Considering De Genne's approximation [3,4] the viscous
 109 dissipation work can be calculated as, $6\pi \mu_d \ln(\varepsilon^{-1}) \frac{R}{\theta_d} \left(\frac{dR}{dt} \right)^2$. Here, we can approximate
 110 the change in radius and time as $dR \approx D_0/2$ and $dt \approx t_c$. The time required for the droplet
 111 to form splat shape (t_c) can be readily used from the traditional droplet impact analysis [8].
 112 Finally, the work due to medium viscosity considering the elemental area of the splat can be
 113 approximated as $\frac{3\pi k_{\mu_m} k_{h_j} D_0^3 We}{8 D_j Re}$.

114 Thus, the non-dimensional equation for the initial spreading ratio ($\xi = D_0/D_j$) is:

$$\xi^3 \left[\frac{9 \ln(\varepsilon^{-1})}{32 \theta_d} + \frac{3 k_{\mu_m} k_{h_j}}{8} \right] \frac{We}{Re} + \frac{\xi^2}{4} [1 - \cos \theta_e] - \frac{k_{h_j}}{8} We - k_{h_j} = 0 \quad (12)$$

115 Again, by replacing only the viscous dissipation work, approximated by lubrication model,
116 with the boundary layer approximation, we can write the non-dimensional energy balance
117 equation for the splat formation as,

$$\frac{1}{4} \frac{k_{\mu_m}}{k_{h_j}} \frac{We}{Re} \xi^3 + \left[\frac{We}{8\sqrt{Re}} + \frac{1}{4}(1 - \cos(\theta_e)) \right] \xi^2 - \frac{k_{h_j}}{8} We = 0 \quad (13)$$

118 **Supplementary Note 1**

119 Parabolic flights generate gravity free conditions in an aircraft by following a parabolic tra-
120 jectory as shown in supplementary figure 1 . They provide a microgravity environment for
121 scientists to conduct research without reaching the outer space but only for 20-25 seconds.
122 During a parabolic or zero gravity flight the aircraft makes a parabolic manoeuvre to achieve
123 a state of weightlessness for minimum 10 seconds to maximum 22 seconds. The parabolic
124 manoeuvre or ellipse arc during a zero gravity flight is divided into three stages: the parabola
125 pull-up, the parabola, and the parabola pull-out as shown in figure.

126

127 Before performing a parabolic manoeuvre, the aircraft needs to be at the 6000m while it
128 is in the horizontal flight mode as well as the aircraft needs to gradually gain a speed of
129 800 – 900 kmh^{-1} before the pull up stage.

130

131 During the pull up stage, the pilot lifts the nose of the aeroplane upward from its horizontal
132 position to an angle of 45°. The pull up stage lasts for 20 seconds while the whole aircraft
133 system experiencing a pull of 1.8 times that of gravity on Earth.

134

135 As the aircraft travel upwards during the pull up stage, the pilot gradually reducing the speed
136 from 800 – 900 kmh^{-1} to 685 kmh^{-1} . Approximately at an altitude of 7800m the aircraft
137 enters the parabolic trajectory, as shown in figure, during which it is in free fall for 22 seconds.

138

Substrate Type	W-CA [°]	DIIM-CA [°]	SFE [mNm^{-1}]	Polar part [mNm^{-1}]	Dispersive part [mNm^{-1}]
CUCL	91.61	69.29	26.51	3.24	23.27
CUCLF	33.42	31.15	69.02	25.27	43.74
CUCLF-W1	48.42	35.73	59.81	18.15	41.66
CUCLF-W16	59.91	35.74	53.46	11.17	41.69

Table 1: Table depicting the water contact angle (W-CA), diiodomethane contact angle (DIIM-CA), surface free energy (SFE), polar and dispersive part of variously treated copper substrate.

139 During the pull out stage the nose of the plane is tilted back to downward to 45° and during
140 this period the pilot gradually start increasing the flight speed until the plane level off. Whole
141 system in the aeroplane again experience a pull of 1.8 times that of gravity on Earth.

142 **Supplementary Methods**

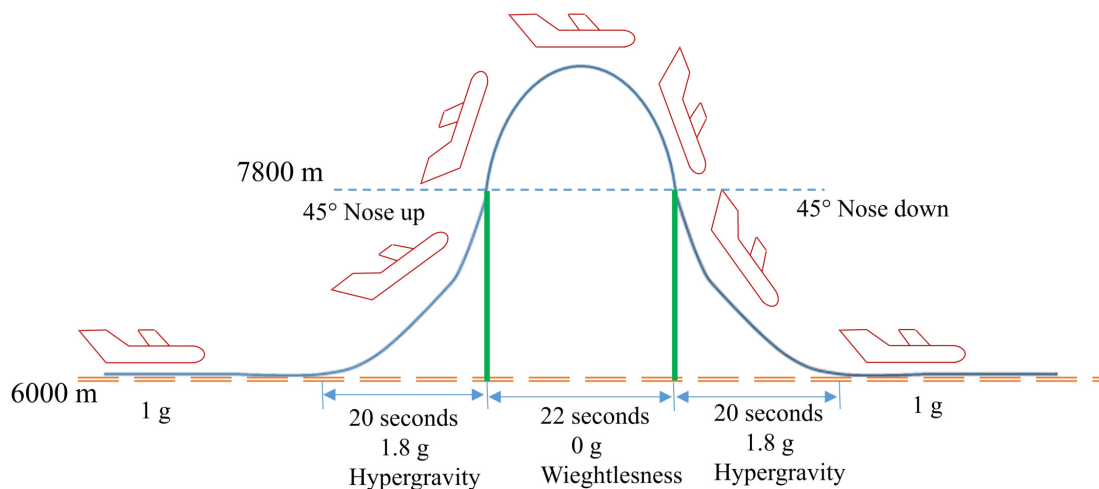

143 Copper substrates used in the study underwent routine testing for historical changes in
144 surface free energy (SFE) using a portable goniometer (Mobile Surface Analyzer (MSA),
145 Krüss Scientific Instruments Inc.) equipped with polar and nonpolar liquids, such as water
146 and diiodomethane (DIIM). As shown in the Table 1 CUCL (Copper cleaned) is a copper
147 substrate cleaned with isopropanol and distilled water. CUCLF(Copper cleaned flamed)
148 undergoes the same treatment with the addition of a flaming step at the end of the process.
149 W1 and W16 stand for week number 1 and 16, respectively, since a substrate has been
150 treated with the flame.

151

152 It can be seen from the results that a significant increase in both polar and dispersive parts
153 can be achieved using the flaming process. The dispersive part exhibits insignificant change
154 over sixteen (16) weeks unlike the polar part that reduced by nearly fifty-five (55) percent.

155

156 **Supplementary Figures**

Supplementary Figure 1: **Parabolic flight trajectory.** Parabolic flight trajectory and the period of hyper-gravity and weightlessness.

Supplementary Figure 2: **Contact angle as a function of volume in different gravitational level.** Variation of dynamic contact angles for different volumes as well as in different gravity level.
